Relating psi to a theory of intuition: using precognition habituation to improve ganzfeld scores

Results:

The major study concerned the subliminal priming of participants with film clips prior to their ganzfeld sessions. In total, 64 trails (32 traditional psi ganzfeld trials and 32 comparison trials with primed targets) were conducted with receiver-sender pairs taking part in a digital real time ganzfeld. Prior to the session, they viewed thematic material from all four potential film clips presented at 40 milliseconds exposures. Although there was a statistically effect showing that the imagery from the clips later reemerged as a major part of the ganzfeld imagery, this concerned the non-target clips more than the target material. First place rankings on the target clips gave only 13.7% hits (MCE 25%) and it may well be that the methodology overloaded the participants with dynamic material. Similar, apparently reversed effects, have been found in other research in subliminal perception. An analysis of the emotional content of the film clips found a highly significant effect relating to sense of awe or “numinosity” but again in the reversed direction.

A further study gave support for the influence of emotional sensitivity in mediating subliminal effect in the form of precognitive habituation effects.
